Tools & Models for Data Science

Deep Neural Networks (1)

Chris Jermaine & Risa Myers

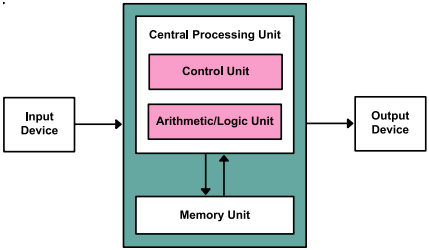
Rice University

What Is a Deep NN?

- At highest level
  - It is a nonlinear function
  - Often represented as a graph

Some History: 1950s

- Interest in artificial NNs started in the 1950's
  - When simple variants were first proposed as a computational model
  - Motivated by the human brain
  - The idea was to model an animal brain
  - Where neurons are either on or off
- Interest in artificial neural networks dwindled as the von Neumann architecture won out

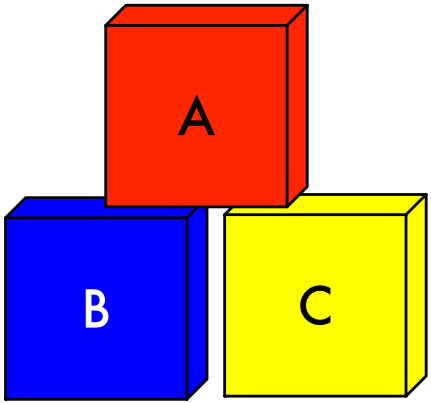


Some History: 1970s

- Then back-propagation was invented in 1975
  - Effectively, it's using gradient descent to train a NN
  - Given examples, learn a model
- Took ANN further from biological roots
- But made them practically usable

Some History: 1980s

- 1980's: the computers couldn't handle the computations
- 2nd "AI winter" 1987 - 1993
  - No serious progress
  - Government felt that scientists were lying to them



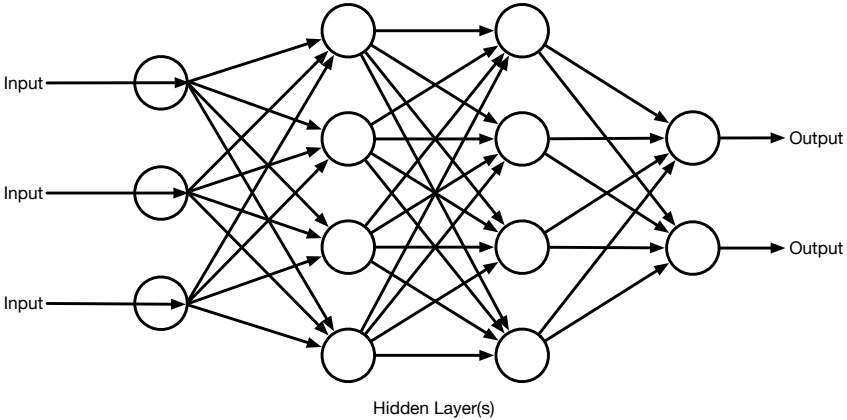
Some History: 1990s

- Interest was renewed, mainly via statistical methods
  - As methods such as SVMs gained popularity
  - Kernel trick surfaced around 1992
- By late 1990's ANNs were almost seen as a joke
  - No one who was hip and with it actually looked at them
  - Why?
  - Way too data hungry
  - Way too computationally expensive to train
  - Alternatives (e.g. SVM) worked pretty well

Some History: 2000s

- But by the end of the aughts, that changed
  - We had tons of data (Google!)
  - We have tons of computational ability
  - Even though Moore's law has stalled out, we have multi-core, GPUs and the like
  - And ANNs are very amenable to parallelization
- Suddenly, ANNs were doing things that amazed everyone
  - Massive increase in accuracy in speech, image recognition
  - Learning to play Go, beat the best players in the world
  - AlphaGo Zero: Learned by playing games against itself

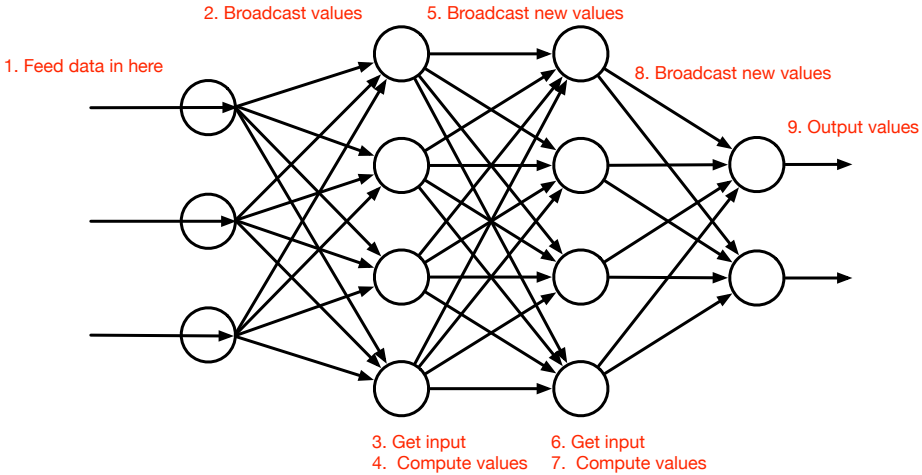
What Does a NN Look Like?



What Does a NN Look Like?

- Inputs
  - Often floating point values
  - Could be a multidimensional feature vector
- Hidden layer(s)
  - Receive input
  - Perform transformation
  - Pass values on
  - Often fully connected
- Outputs
  - Often probabilities
  - Reflect levels of certainty

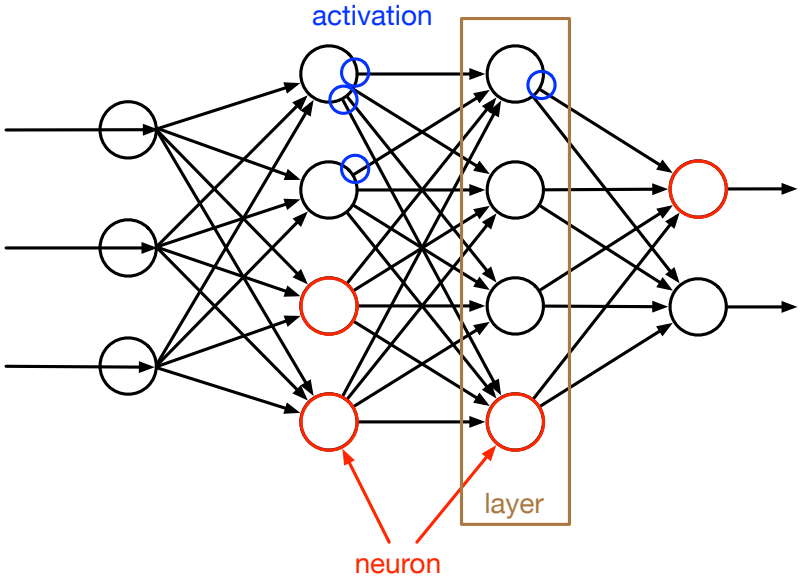
What are the Steps in NN Processing?



Terminology

- The circles are called “neurons”
  - Are little computational units
  - Function they compute is always chosen to be differentiable
  - Since learning is via gradient descent
- Output of a neuron is called an “activation”
- Neurons are organized into “layers”
  - In simplest case, layers take input only from preceding layer

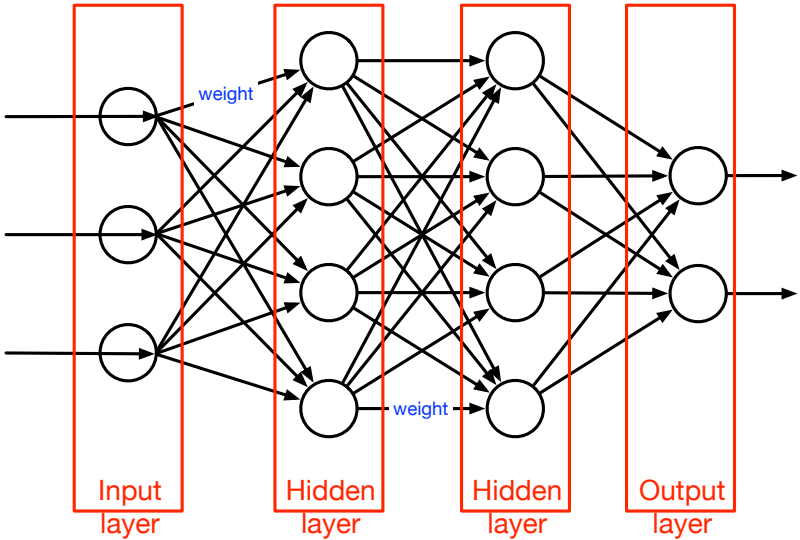
NN Terminology



Terminology (cont'd)

- Top/right layer in deep NN is the "output layer" (layer t for "top")
- Bottom/left layer in deep NN is the "input layer" (layer 1)
  - Activation of input neurons read directly from input features
- Are one or more "hidden layers" between those two (layers $1 < i < t$)
- Each link between neurons has a "weight"
  - Input into a neuron is the weighted sum of activation that travels over all edges that point into the neuron

NN Terminology

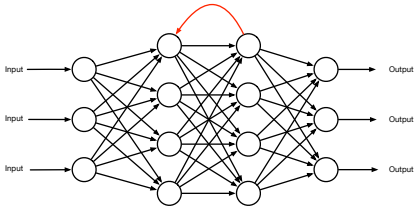


Terminology (cont'd)

- Today we'll assume a "fully connected" NN
  - That is, each neuron in layer $i > 1$ takes input from all neurons in layer $i - 1$
- But there are other connection patterns between layers
  - Example: convolutional layers
  - Used extensively in image processing
  - Where subsets of neurons are constrained to only work on contiguous regions of input data

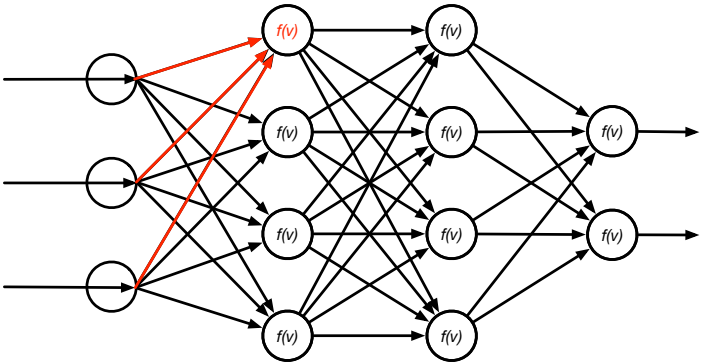
Simplest NNs

- Are called “feed-forward” NNs
  - Because activations only flow forward thru network
  - Flow from input layer
  - Thru hidden layers
  - And out of the output layer
- Other options include “recurrent” NNs
  - In an RNN, input from upper layer fed recursively into input in lower layer



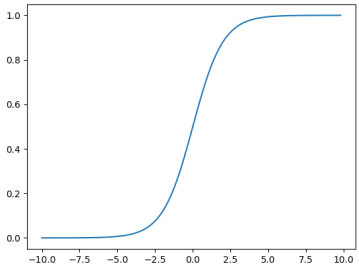
What Function Does Each Neuron Compute?

- Need each neuron to compute some function $f(v)$
  - v is weighted sum over input activations
  - $f(v)$ is often simple and differentiable



What Function Does Each Neuron Compute?

- Typically a “sigmoid” function
  - So neuron goes from “off” to “on” (like a soft binary gate)
  - Output is a floating point number
  - But smoothly, so differentiable (gradient descent once again!!)



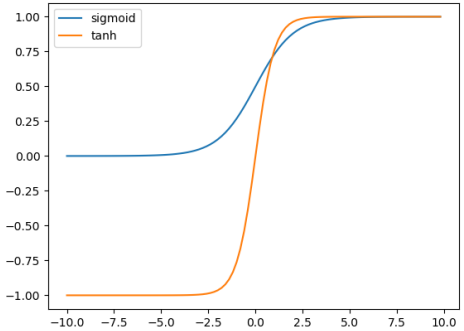
Classic Sigmoid Functions

- First, the hyperbolic tangent function

$$y = \tanh(v)$$

- Second, the logistic function

$$y = (1 + e^{-v})^{-1}$$

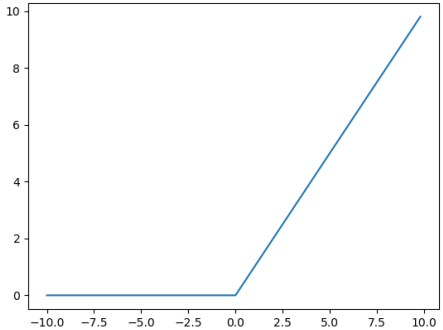


Modern Sigmoid Function

- ReLU “Rectified linear unit”

$$y = \max(0, v)$$

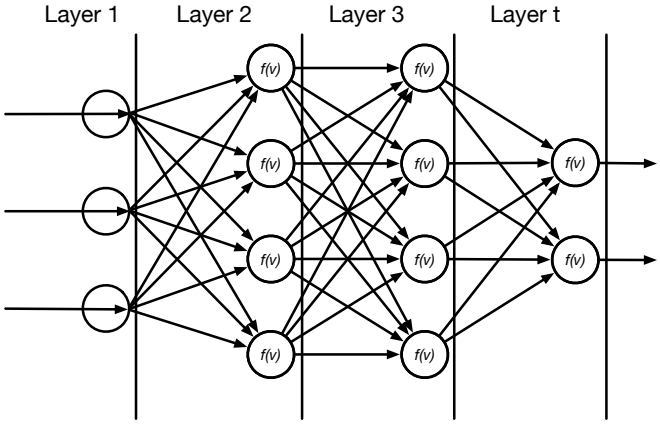
- 0 or pass through the input value



Evaluation of a Feed-Forward NN

- Typically done via vectorized operations... fast!
- How to push activation thru a network...
  - Let y_i be a row vector denoting output of ith layer
  - Define $y_1 = x$, the input data
  - Let f denote the vector-valued function applying the activation function to each item in a vector
  - Let W_i denote the matrix of weights connecting layer $i-1$ to layer i
  - If layer $i-1$ has n neurons, layer i has m neurons, then W_i has n rows, m columns
  - And $y_i = f(y_{i-1} \times W_i)$

NN Evaluation



$$\begin{bmatrix} y_{1_1} & y_{1_2} & y_{1_3} \end{bmatrix} \quad \begin{bmatrix} y_{21} & y_{22} & y_{23} & y_{24} \end{bmatrix} \quad \begin{bmatrix} y_{31} & y_{32} & y_{33} & y_{34} \end{bmatrix} \quad \begin{bmatrix} y_{t1} & y_{t2} \end{bmatrix}$$

$$W_2 = \begin{bmatrix} w_{11} & w_{12} & w_{13} & w_{14} \\ w_{21} & w_{22} & w_{23} & w_{24} \\ w_{31} & w_{32} & w_{33} & w_{34} \end{bmatrix} \quad W_3 = \begin{bmatrix} w_{11} & w_{12} & w_{13} & w_{14} \\ w_{21} & w_{22} & w_{23} & w_{24} \\ w_{31} & w_{32} & w_{33} & w_{34} \\ w_{41} & w_{42} & w_{43} & w_{44} \end{bmatrix} \quad W_4 = \begin{bmatrix} w_{11} & w_{12} \\ w_{21} & w_{22} \\ w_{31} & w_{32} \\ w_{41} & w_{42} \end{bmatrix}$$

Evaluation of a Feed-Forward NN

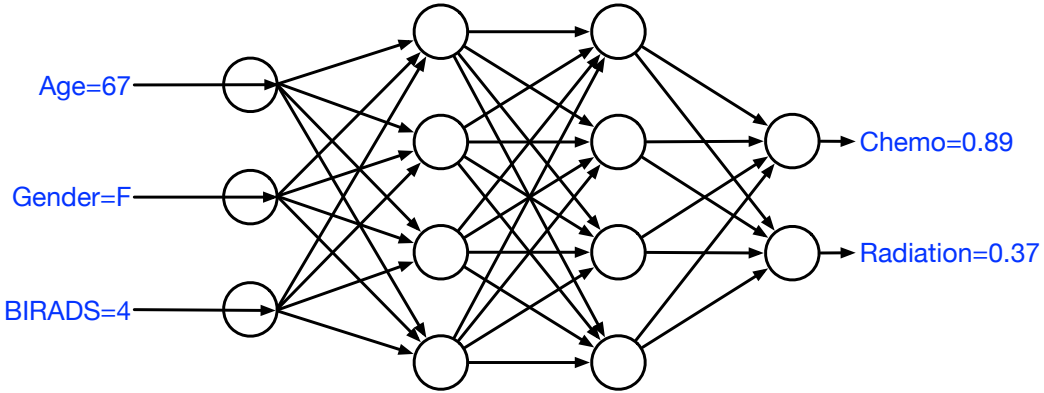
- It's all about matrix & vector multiplication
- You could write lots of loops in Python
- Recall, we've talked a lot about vector operations
- GPUs are really good at linear algebra
- So, write linear algebra

The input

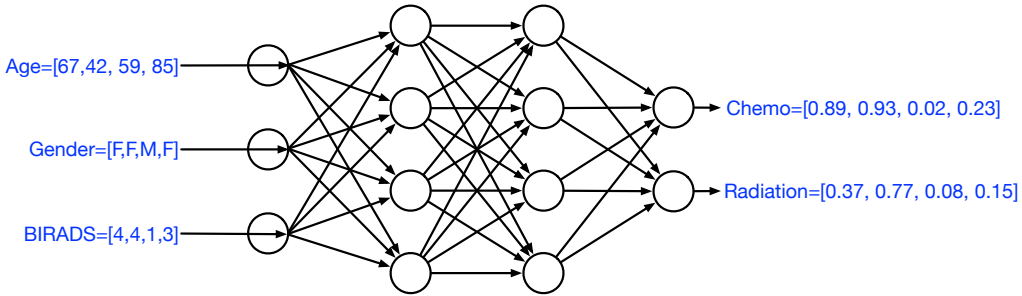
In practice

- We send multiple inputs through the network at the same time
- So, y is a matrix, not a vector
- Why?
  - It's more efficient
  - Theoretically, it's the same complexity, but in practice, it's different

NN Example



NN Example with Multiple Inputs



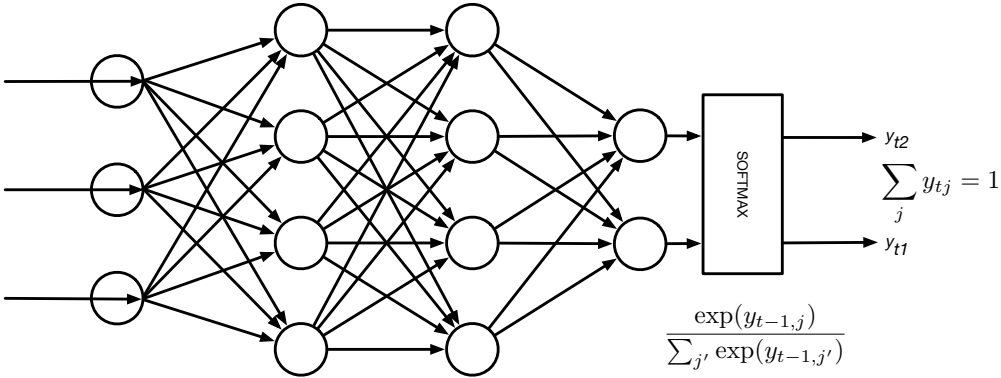
Producing Outputs

- NNs classically used for classification
  - Output is function of activations of second-to-last layer
- Often, we want certainty - e.g. a probability
- Typically we use a “softmax” function
  - That is, neuron j at layer t (the “top” layer) outputs:

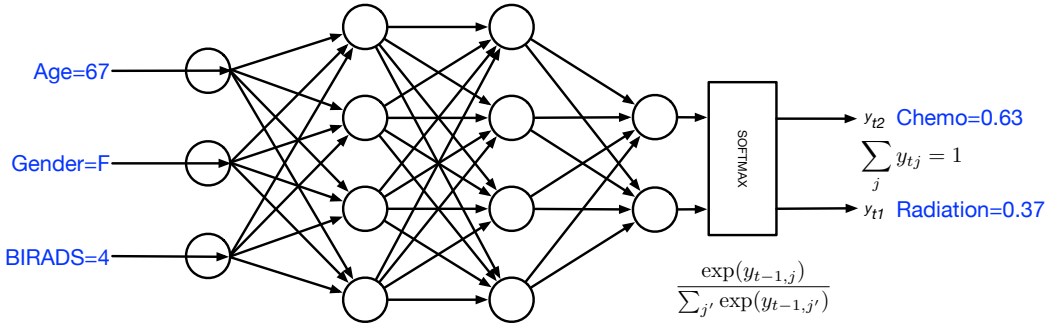
$$\frac{\exp(y_{t-1,j})}{\sum_{j'} \exp(y_{t-1,j'})} = \frac{\texttt{output of previous layer}}{\texttt{normalization term}}$$

- Since all y_t values then sum to one...
  - $y_{t,j}$ typically viewed as the probability that correct class label for data y_1 is j

NN with Softmax



NN Example



Age=67
Gender=F
BIRADS=4
SOFTMAX
y_{t2} Chemo=0.63
$\sum_j y_{tj} = 1$
y_{t1} Radiation=0.37
$\frac{\exp(y_{t-1,j})}{\sum_{j'} \exp(y_{t-1,j'})}$

Another Example Classification

- Want to solve a classification problem
- Chihuahua or muffin?
- Push the picture through the FF network
- End with two neurons
  - Chihuahua
  - Muffin

Using Softmax

- Could take the max of the two outputs
- But it's a smooth function – we have degrees of "On"
- The **max** function is not differentiable
- Use **softmax** instead
- Gives us Pr[Chihuahua] and Pr[Muffin]
- Sample using probabilities to choose one

Another Example

- E-Discovery: Want to identify emails that are relevant to a court case
- Say there are 100 topics of interest to the case
- Crowd source relevant example emails fo each topic
- Each email might contain any number of the topics
- Goal: identify additional emails that are relevant to each topic

Yet Another Example

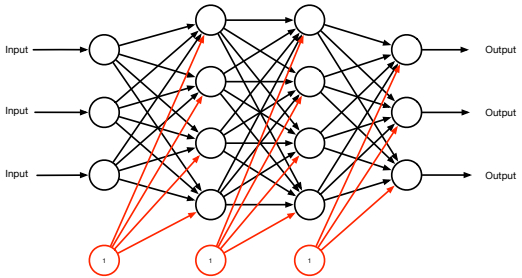
- Want to identify objects in a image
- Each image may contain multiple objects
- Push the pictures through the FF network
- End with a neuron for every object you want to identify
  - Cat
  - Dog
  - Puppy
  - Tree
  - Mug
  - ...
- The output of each neuron gives the confidence of that object being in the image

Bias

- Just like in regression....
  - We want to be able to bias output of each neuron
  - So, the neuron is not on/off 50% of the time with totally random input
  - Maybe we want it on just 5% of the time with random input
  - Basically like adding an intercept term
- How to do this?

Bias

- Easy!
  - Just like in LR
  - Have a special neuron at each layer
  - It always outputs the value 1
  - Regardless of its inputs
  - Then the last row of each W_i will have biases
  - Since $w_{i,j} \times 1$ will be added into input to each neuron in layer $i+1$



Summary

- What is a NN?
- What are the components of a NN?
- What kinds of problems can it solve?

Learning

- What are the weights?
- Accomplished via gradient descent
- Gives rise to the famous “back-propagation” algorithm
